Assessing the Effects of Corruption and Crime on Firm Performance

December 2000
I. Introduction

A myriad of empirical studies show that countries with high levels of corruption have lower growth rates. Few studies, however, have looked at the implications of corruption for the prospects of firms. This paper aims at filling this void by studying the effects of corruption upon the economic outcomes of private firms in 29 countries.

In particular, this paper uses a survey of private firms to assess the effects of corruption upon the economic prospects of firms. First, the paper studies whether corruption and crime affects sales, investment and employment growth at the firm level. Second, the paper examines whether bribes and illegal payments by firms reduces bureaucratic interference. In addition, the paper studies what firms are more likely to complain about crime and corruption, and whether corruption indicators based on private sector surveys are consistent across surveys and methodologies.

The paper finds that corruption and crime substantially reduces sales growth. These effects are apparent even after firm characteristics country fixed effects are taking into account. Corruption, and in particular crime, also lowers investment and employment growth, though these effects are smaller and not always statistically significant. This paper also finds that corruption and bureaucratic interferences are positively correlated at the firm level, which casts serious doubts on various theories that postulate that corruption may increase efficiency by allowing firms to circumvent government regulations. On the whole, the results of the paper suggest that corruption and crime substantially reduces firm competitiveness and that corruption is quite unlikely to have any positive effects.

The results also show that corruption and crime are ubiquitous in Latin America. In this region, 60 percent of the managers interviewed report that corruption is an obstacle to doing business, 28 percent reported that bribe payment are common in their line of business, and 30 percent that at least one government official requested bribes during 1999. Further, corruption appears to affect all types of firms, irrespective of tenure, size, location, sector and type of business. In contrast, bureaucratic red tape is not more common in Latin
American countries than in O.E.C.D countries. In both cases, managers reported that about five percent of senior's management time is spent dealing with bureaucrats.

The rest of this paper is organized as follows. Section II presents an overview of the literature on the causes and consequences of corruption. Section III describes the data and presents the results on the incidence of crime and corruption. Section IV presents the results on the effects of corruption upon economic outcomes. Section V presents the results on the interplay between corruption and bureaucratic interference. And section VI concludes.

II. Literature Overview

The growing interest in governance issues has spurred a huge scholarly literature about the causes and consequences of corruption. Although a comprehensive survey of this literature is well beyond the scope of this paper, we try here to summarize some of the main arguments brought up by the scholars doing applied research on the topic. The goals are to facilitate the interpretation of the results presented below and to offer the uninitiated a quick peek into a burgeoning literature.

Figure 1 displays the main factors associated with the presence of corruption. The determinants of corruption are shown on the left-hand side and its main effects on the right-hand side. Let's start with the determinants. The conjunction of rents and unaccountable public servants will give rise to corruption. Obviously, the higher the rents, and the fewer the checks on public servants, the higher will be the opportunities for corruption.

The more regulated an economy and the larger the amount of resources administered by the state, the higher will be the rents in the hands of public officials. Government regulations give public officials the right to disperse valuable rents, increasing the scope for corruption. Bloated budgets give public officials greater ability to transfer public resources to their cronies, equally increasing the scope for corruption. Public rents are also much higher in countries with large endowments of natural resources, which is why many champions of corruption are oil producing countries. Likewise, public rents controlled by bureaucrats are
more valuable in economies with fewer opportunities and less competition, which is why countries less open to foreign trade tend to be more corrupt.

What makes public officials accountable? We can distinguish between two different sets of factors: the first set has to do with the extent of democratic freedoms and the second with the effectiveness of legal institutions and the pervasiveness of anticorruption norms. Civil liberties and political rights lower corruption by giving people not only the liberty to denounce corrupt officials but also the ability to vote out dishonest politicians. Obviously, the more informed and participative the electorate, the lower will be the ability of public servants to get away with corruption. A freer and more influential press will also reduce the scope of corruption, as will the existence of well-functioning institutional checks and balances. Greater political instability will increase corruption, because instability generates the perception among politicians and public officials that the probability of winning elections doesn’t depend on their actions, thus increasing the incentives to extract rents.

Institutional factors also reduce corruption (and by institutional we mean both formal laws and informal norms). Common law systems, originally designed to protect people against arbitrary expropriations by the sovereign, reduce corruption by giving private parts the edge in their disputes with the state. The opposite is true for civil law systems, originally used by the sovereign as instruments for state building and the regulation of economic life. Social norms that encourage the challenge of authority by common citizens also reduce corruption, mainly by increasing public willingness to denounce malfeasant politicians and bureaucrats. These norms are usually more widespread in protestant societies than in societies in which more hierarchical religions (Catholicism, Eastern Orthodoxy, Islam) dominate. Not surprisingly, then, corruption will tend to be lower in protestant societies. For the same reasons, corruption will tend to be lower in more educated societies, which implies that corruption will fall as income per capita increases.
Figure 1. Causes and Effects of Corruption

Existence of Rents:

Absence of Democracy:

Institutional Variables:
Civil Law Systems: La Porta et al., 1999.
Excessive Centralism: Shleifer and Vishny, 1993

Effects of Corruption:
Corruption will also be higher if government agencies have complete control of important government services. If different agencies compete to offer the same service, competition will drive rents toward zero. If only one agency can offer the service, however, rents will be substantial, given public servants ample scope to collect bribes. This argument implies that federal states, in which sub-national units compete to attract business and sell government services, will be less corrupt. Moreover, one can argue that decentralization (and hence federalism) lowers corruption by facilitating the public control of government officials.

Unfortunately, the empirical literature on the causes of corruption doesn’t permit to rank the factors mentioned above. Different authors emphasize different factors, and students of this sprawling literature are often at loss when trying to draw some conclusions. Perhaps the main (and disheartening) conclusion is that cultural and historical factors, many of which are not amenable to policy manipulation, are as important as current policies in the determination of corruption. Thus, Protestantism is as important as democratization and spontaneous political participation as important as institutional check and balances. Further, definitive conclusions are unlikely, if only because the various determinants of corruption interact in complex ways.

The right-hand side of the Figure 1 lists the main consequences of corruption brought up in the literature. First and foremost, corruption is negatively correlated to economic growth. Whether or not this correlation actually means that corruption is bad for growth is still a contentious issue, though most empirical studies appear to confirm it. The pathways whereby corruption affects growth are rarely spelt out in the literature. Increasing uncertainty, the misallocation of talent and smaller rates foreign direct investment are among the most frequently mentioned pathways.

Corruption affects not only the levels of foreign direct investment, but also its composition. If corruption is high enough, then foreign investors will avoid the host country altogether. If corruption is not prohibitive but still present, foreign investors will prefer to associate with local partners because of the importance of their knowledge about how to deal with
bureaucrats. If corruption is not a problem, then foreign investors, especially when keen about protecting intangible assets, will prefer wholly-owned subsidiaries.

Corruption also increases the level of unofficial activity. Many entrepreneurs will prefer to go underground in order to avoid arbitrary expropriations by malfeasant officials. If corruption is very high, the unofficial economy will expand, often reaching a substantial fraction of total economic activity. As a result, tax revenues will fall and with them the size of the government. Not surprisingly, then, corrupt governments tend also to be small governments. Corruption also affects the composition of government expenditures. Specifically, corrupt officials will steer investments toward infrastructure (where bribe collection is more expeditious) and away from health and education (where bribe collection is more involved).

Finally, this literature suggests that corruption and economic development (or the lack thereof) feed on each other. Economic development in general and the spread of education in particular lowers corruption. But dwindling corruption can spur economic development. This virtuous circle is an example of the positive reinforcement between government quality and economic developments; arguably the main mechanism underlying the differences in wealth among the nations. And still the biggest mystery of economics.

III. Corruption and Crime in the Private Sector Survey

Corruption is often defined as the misuse of public power for private gain. This definition encompasses a wide range of phenomena, from a police officer who accepts money from drug traffickers, to a custom agent who extorts businesses and to a politician who appropriates royalties. As different as these phenomena are, they may be driven by the same causes and have similar effects upon economic and social outcomes.

One should distinguish at least between two different forms of corruption. The first form refers to an illegal transaction involving public officials and private parts. This includes bribe collection by public officials and illegal payments by private businesses. The second
form doesn't involve private parts and refers mainly to the illegal misappropriation of public property by public officials, including bureaucrats, elected politicians and judges.

These forms of corruption affect the economic prospects of firms through different pathways. Bribes raise operational costs and create uncertainty. Exporting firms, for example, will be less competitive in a country where port officials charge hefty bribes to complete pre-shipment inspections. Licit businesses will suffer as well if corrupted officials allow illegal practices to go unchecked. Software firms, for example, may be driven out of business if "captured" officials decide not to enforce copyright regulations.

The stealing and pilfering of government resources by public officials do not have direct effects on the economic prospects of firms, but can have huge indirect effects. Public finances will deteriorate, creating uncertainty and raising the cost of credit. Infrastructure will crumble, public services will worsen and the general climate of business will suffer as well.

Not surprisingly, these two forms of corruption tend to go hand in hand. If a bureaucrat can collect bribes without fear of punishment, chances are that she will also have enough leeway to unduly appropriate public money. Similarly, if a politician has the power to award contracts to his cronies, probably he will also be able to capture some government rents. These examples notwithstanding, it pays to distinguish between these two forms of corruption, if only to fully understand exactly what we measure when we use private sector surveys to measure corruption.

The data used in this paper is based on a private sector survey conducted by the World Bank and the Inter-American Development Bank in 1999. About 100 middle and top managers in 29 countries (20 of them from Latin American) were queried about their perceptions on several areas of government performance, including predictability of policies, reliability of the judiciary, problems with corruption, crime and public services.
This survey is a sequel of a survey conducted by the World Bank in 1997 as part of World Development Report of that year.\(^1\)

The private sector survey includes several questions about firm characteristics, including size, location, tenure, and sector. Sector quotas were used in all countries: roughly 40 percent of the firms surveyed in each country come from manufacture. None of the country samples was intended to be representative to the universe of firms of the country, which should be kept in mind when comparing country means.

The survey includes at least six questions about corruption. The first question asks the respondents to judge the extent to which corruption and crime are obstacles to the operation and growth of their business. The second question asks the respondents whether firms in their line of business often pay bribes to get things done. The next three questions focus on various aspects of the bribe collection process: whether firms know in advance the value of the bribes they have to pay, whether firms can count on services being delivered after paying bribes and whether firms have to pay bribes not to one but to several officials. In addition, the survey includes several questions as to whether officials from specific government offices (e.g., tax and procurement agencies, customs and courts) and state-owned enterprises (e.g., power and telephone companies) requested bribes during 1999.

Table 1 presents the sample means of the questions described above. Questions containing more than two options were dichotomized so that the averages could be interpreted as percentages. While 46 percent of the respondents stated that corruption is an obstacle to the operation and growth of their firms (corr1), 23 percent stated that firms in their line of business often pay bribes (corr2). Similarly, 12 percent of the respondents report that they often have to pay bribes to more than one official for the same service (corr5), 13 percent report that custom officials requested bribes during 1999 and 30 percent that officials from at least one of the agencies listed did the same (corr6). Finally, 53 percent reported that crime is an obstacle to doing business (crime).

\(^1\) See World Bank (1997) for a thorough description of this survey. The O.E.C.D. countries included in the survey are Canada, France, Germany, Italy, Portugal, Spain, Sweden, United Kingdom, and the United States. The Latin American countries are listed in Figure 2.

Table 1 also shows the stark differences between Latin American and O.E.C.D countries in terms of corruption and crime. As measured by any of the variables at hand, corruption is much greater in Latin America than in O.E.C.D. countries. Whereas almost 60 percent of the respondents from Latin America state that corruption is an obstacle to doing business, only 17 percent of the respondents from O.E.C.D countries report a similar opinion. As for whether bribes are common in their line of business, 28 percent of the respondents from Latin America and 12 percent of the respondents from O.E.C.D countries said to agree with that statement. Concerning crime, the differences are even more striking: while 22 of the respondents in O.E.C.D countries state that crime is an obstacle to their business, 67 percent of the respondents in Latin American countries state the same.
Figure 2. Corruption As an Obstacle to Doing Business

Figure 2 shows the percentage of respondents in each Latin American country who reported that corruption is an obstacle to doing business. This percentage is the largest in Bolivia, Ecuador and Mexico, and the lowest in Uruguay, Chile and Trinidad and Tobago. Although corruption is ubiquitous in Latin America, it has different faces in different countries.

Table 2 shows that customs officials are the most corrupt officials in Colombia, Costa Rica, Uruguay and Venezuela, tax inspectors are in Argentina, Bolivia, Brazil and Panama, and telephone workers are in Ecuador, Haiti and Honduras.

Almost all of the questions included in Table 1 refer to the existence of illegal transactions involving private and public officials (the first form of corruption mentioned above). Only the first question, which asks whether corruption is an obstacle to doing business, can capture some general perceptions about the misuse of public resources by unscrupulous public officials (the second form of corruption mentioned above). In consequence, cross-country comparisons based on this survey refer mainly to the first form of corruption and should be interpreted as such.

In what follows, we focus on tree measurement issues. First, we investigate the degree of association at the country level between the variables listed in Table 1. Second, we
investigate whether or not the same variables vary across different surveys. And last, we investigate what attributes make firms more likely to suffer from corruption and crime.

**Correlation between Measures of Corruption and Crime**

Table 3 displays the pairwise correlation coefficients between the country means of the different variables listed in Table 1. Most variables are highly correlated. In countries where most respondents state that corruption is a major obstacle to doing business (corr1), they also state that bribes are common in their line of business (corr2). Similarly, in countries where most respondents state that corruption is an obstacle (corr1), they were also much more likely to report that public officials requested bribes during 1999 (corr6). Perceptions about whether corruption is an obstacle to doing business are also aligned with perceptions about whether crime constitutes a similar hurdle.

See Table 1 for variable definitions.

Table 4 looks in greater detail at the connection between corruption and crime. Countries were divided in two groups according to whether or not more than half of the managers interviewed report that corruption is an obstacle to doing business. Similarly, countries were divided in another two groups according to whether or not the same managers report that crime is an obstacle to the operating of their business. Table 4 shows that in only one country these partitions do not coincide, which points to the fact that perceptions about the prevalence of crime and corruption are strikingly close. Thus, firms in many Latin America countries are subject to a double curse: on the one hand, they lack protection from theft and
violence and, on the other, they are at mercy of corrupt public officials.\textsuperscript{2} It goes almost without saying that doing business under those circumstances could be a heroic activity.

\end{table}

\textit{Cross-survey Correlations}

As mentioned above, the private sector survey is a sequel of a survey conducted by the World Bank in 1997. Several questions about corruption and crime, and many others about policy predictability, bureaucratic red tape and government quality in general, were included in both surveys, allowing comparisons between the two. The original survey comprised 69 countries, including 58 from developing regions and 9 from Latin America. The new survey comprised 29 countries, including 20 from Latin America. Only 15 countries were included in both surveys, meaning that cross-survey comparisons are limited to this small sample.\textsuperscript{3}

These comparisons should shed light not so much on the temporal variation of the variables under analysis, as on the reliability of the country means as indices of corruption. This is important because samples are not necessarily representative of the countries under consideration. If indices are similar from one survey to the next, this will give credence to cross-country comparisons based on them. Otherwise, one would suspect that such comparisons are flawed.

Table 5 presents a comparison between the two surveys. For three of the six variables under analysis, there seems to be a high degree of correlation between the two surveys. The results show, in particular, that country means based on questions as to whether corruption

\textsuperscript{2} This fact is referred to as the lawlessness syndrome in the World Bank (1997).

\textsuperscript{3} These countries are Bolivia, Brazil, Canada, Colombia, Costa Rica, Ecuador, France, Germany, Italy, Mexico, Portugal, Spain, United Kingdom, United States and Venezuela.
and crime are obstacles to doing business (corr1 and crime) and bribes are common (corr2) vary very little from one survey to the next. By contrast, means based on questions as to whether firms know the values of the bribes and can count on services being delivered (corr3, corr4 and corr5) yield much more volatile results. These results indicate that whereas direct questions about the existence of corruption yield reliable corruption indices, more complex questions about the process of corruption do not.

Table 5. Cross-Survey Correlations

Figure 3 shows that there exists a high correlation between the corruption indices derived from the 1999 version of private sector survey and a composite index of corruption derived by Kaufmann and his collaborators at the World Bank. It’s worth noting that the Kaufmann index is based partially on country means derived from the private sector survey carried out by the World Bank in 1997; values that are in turn highly correlated to the country means derived from the survey used in this paper.

In sum, the previous results suggest that survey means are enough to gauge differences in corruption among countries.

Corruption, Crime and Firm Characteristics

Data from the private sector survey can be used to study what type of firms are more likely to report that corruption and crime affect them one way or another. Insofar as learning about the victims can teach us something about the nature of the crime, this analysis can

\[4\] Kaufmann, Krany and Zoido-Lobaton (1999) built an index of corruption by combining information from several existing indices using an unobserved component method. Most corruption indices are based on either survey of experts or surveys are firms. The former involved only a few experts per country whereas the latter usually involved hundred or more forms per country.
provide some insights about the mechanisms of corruption and its consequences for competitiveness.

We use the following empirical model to study the connection between the incidence of corruption and firm characteristics:

\[ Y_{ij} = c + X_{ij} \beta + \lambda_j + \epsilon_{ij}, \]  

where \( Y_{ij} \) is dummy variable showing whether the manager of firm \( i \) that is located in country \( j \) report the incidence of corruption, \( X_{ij} \) is a vector of firm characteristics (including sector, size, tenure, location, whether the firm has foreign or state ownership, and whether the firm sell goods or services to the government), \( \lambda_j \) is a country effect and \( \epsilon_{ij} \) is an error term. Country effects are included to control for unobserved country attributes. One may argue, for example, that individuals living in more corrupt countries have looser standards to judge corrupt practices. Country-fixed effects control for these differences, among many others.
In order to minimize spurious correlations between perceived corruption and firm attributes, we control for the propensity of managers to complain without reason. If managers of small firms are more likely to complain about all aspects of the business environment, we may wrongly conclude that small firms are more liable to suffer from corruption and crime. We use the average rating of the quality and efficiency of five public services: roads, postal service, power, telephone and water to approximate a respondent’s tendency to complain. Because objective ratings of these services should not differ much across firms, actual differences in the ratings can be interpreted as differences among managers in their tendency to complain indistinctively about all aspects of the business environment.\(^5\)

Table 6 shows the average values of the main independent variables used in the analysis. The average values blur important variations among countries. In the United Kingdom only five percent of the firms included in the survey have more than 500 employees, in Colombia more than half exceeds this value. In Italy over 60 percent of the firms have business with the government, in Portugal only 20 percent do. In Sweden 60 percent of the firms are located in small towns, but in Portugal, Peru, Canada and Mexico only ten percent are located there. Importantly, these differences reflect not so much differences in the structure of production of the countries under analysis, as differences in the sampling procedures.

We use four different dependent variables: whether corruption is an obstacle to doing business (corr1), whether bribery is common in one’s line of business (corr2), whether at least one of government agencies listed in Table 1 requested bribes in 1999 (corr6), and whether crime is an obstacle to doing business (crime). The same specification was used in all four cases so that we can evaluate the extent to which the results are robust to the changes in the definitions of the dependent variable.

Table 7 presents the estimation results. Results are based on a Probit model, but do not differ much if other estimation methods are used. There seems to be no systematic

\(^5\) This correction was used by Kaufmann and Wei (1999) in a similar context.
relationship between firm characteristics and corruption apart from its higher incidence among small firms. Neither firms that sell goods and services to the government nor firms located in the capital of the country nor those in manufacturing appear more likely to suffer from government arbitrariness in the form of corruption. There is slight evidence that firms with some government ownership are less likely to suffer from corruption, but this result is not always significative and may be driven not so much by actual differences in corruption, as by differences in the willingness to report corrupt practices (arguably smaller in firms with government ownership). Perceptions about the damaging effects of corruption and its prevalence in one’s line of business do not appear to vary consistently across firms.

As in the case of corruption, small firms are more likely to perceive crime as an obstacle to business operations than larger firms. Firms located in the capital and in large cities as well as firms that have some government ownership are less likely to complain about crime. The negative connection between city size and crime is at odds with evidence from victimization surveys, suggesting that the causal factors underlying crime affecting businesses differ from those underlying crime affecting people.⁶

There are some worthwhile differences between Latin America and the developed world in the patterns of corruption across firms. In O.E.C.D. countries firms that have sales to the state sector tend to complain more about corruption, while in Latin America they do not.

⁶ See, for example, Gaviria and Pages (2000).
However, the negative connection between firm size and the incidence of corruption is stronger in Latin America than in the developed world. One can speculate that while in developed countries corruption affects mainly firms that have deals with the government (corruption is often no more than a calculated nuisance for these firms), in Latin America corruption affects mainly smaller firms.

Small firms and firms located in the country side are the baseline groups

Three main conclusions can be drawn from the previous analysis. First, corruption and crime go hand in hand. Second, small firms are more likely to suffer from crime and corruption, suggesting that these problems may have an especially detrimental effect upon new entrepreneurs. And third, mean country averages appear to be reliable corruption indices in that they do not vary much between consecutive applications of the same survey. This last result notwithstanding, these indicators may not capture corruption by public
officials that do not directly affect private businesses (e.g., the pilfering of public money by unscrupulous public officials).

IV. Corruption, Crime and Economic Outcomes

Recent empirical research shows that growth rates tend to be lower in countries with higher levels of corruption. Various mechanisms have been mentioned to explain this empirical regularity: corruption depresses foreign and domestic investment, reduces innovation and increases the operating costs of firms. In this section, we use the private sector survey to examine the effects of corruption on the economic outcomes of firms. It goes almost without saying that if corruption is bad for growth, the firms most affected by it should present, all else equal, worse outcomes in terms of sales and investment growth and job creation.

The private sector survey includes several questions about the past performance of firms. Managers were asked to estimate the growth of their companies’ sales, investment, exports, employment and debt over the last three years. We assume that these answers capture the recent performance of the firms under analysis. Indirect evidence gives credence to this assumption. For one thing, country means are highly correlated to the average GDP growth (see Figure 4). For another, the best performing firms in the sample are, exactly as would be expect, younger firms with foreign ownership that export part of their production. Interestingly, firms that have some type of government ownership are the worst performing of all.

We focus here on three indices of performance: growth of sales, investment and employment. The three indices are highly correlated at the firm level. The correlation coefficient between sales growth and employment growth is 0.58 and all pairwise coefficients are greater than 0.45. The mean growth of sales in the whole sample is 9.2%, the mean growth of investment 12.4%, and the mean growth of employment 3.4%. Mean

---

7 See, for example, Mauro (1995) and World Bank (1997).
8 The correlation coefficient between GDP growth and average sales growth is 0.64. The coefficients between GDP growth, on the one hand, and investment and employment growth, on the other, are 0.73 and 0.61.
growth rates of employment and sales are much higher in O.E.C.D. countries than in Latin American countries. For employment, the mean rates for O.E.C.D and Latin American countries are 7.6% and 1.5%, respectively. For sales, the corresponding values are 14.2% and 7.0%.

Country means of firm performance and corruption indicators are highly correlated. The correlation coefficient between mean sales growth and the percentage of managers that state that corruption is an obstacle to doing business is 0.42. Somewhat smaller values, though still substantial, are obtained if other indicators of economic performance and corruption are used instead. However, cross-country correlations based on average indices can have serious drawbacks, if only because they can be driven by differences in country characteristics that are correlated with both economic activity and corruption. In what follows, we abstract from cross-country differences and focus on the relationship between economic performance and the incidence of corruption at the firm level.

Our empirical analysis is based on the following empirical model

\[ S_{ij} = c + \delta \text{Corru} + X_{ij} \beta + \lambda_j + \nu_{ij}, \]  

(2)
where $S_{ij}$ is the rate of growth of sales of firm $i$ in country $j$, Corrup is an indicator of corruption, $X_{ij}$ is a vector of firm characteristics (including sector, size, tenure, location, whether the firm has foreign or state ownership, and whether the firm sell goods or services to the government), $\lambda_j$ is a country effect and $\varepsilon_{ij}$ is an error term. A negative value of $\delta$ would indicate that corruption negatively affects economic performance at the firm level.

Controlling for the propensity of firm managers to complain is paramount in this case. If managers complain indistinctively about everything, a positive but spurious correlation between bad economic outcomes and reported corruption would ensue. As before, we use the rating of public services to approximate the propensity of respondents to gripe. Because objective ratings of these services should not differ much across firms, differences can be interpreted as differences among managers in their tendency to complain indistinctively about all aspects of the business environment.

We estimate Equation (2) using OLS. We control for all firm characteristics included in Table 6 and for country specific fixed effects. Controlling for country fixed effects is important given the aforementioned high correlation between countrywide indices of firm performance and corruption. We use four distinct corruption indicators, all of which were defined in the previous section. corr1 equals one if the respondent stated that corruption is a significant obstacle to doing business. corr2 equals one if the respondent reported that bribes are common in their line of business. corr6 equals one if the respondent reported that public officials requested bribes during 1999.\footnote{The other corruption indicators are less reliable and were not used in this case. Unreported results show that they have no consistent relationship with bureaucratic delay.} And crime equals one if the respondent reported that crime is an obstacle to doing business. The implicit assumption of our analysis is that firms that answer affirmatively to these questions are more likely to harassment by public officials. This assumption seems reasonable for all indicators considered, perhaps with the exception of corr2.

Table 8 shows the effect of corruption and crime upon the rate of growth of sales. These rates are almost three percentage points (or 30 percent) lower in firms where managers
report that corruption is an obstacle to doing business than in firms where managers report otherwise. Similarly, rates of growth of sales are 35 percent lower in firms where managers complain about crime than in firms where managers do not. The same differences are a bit smaller and no longer statistically significant if alternative corruption indicators are used.

This evidence suggests that crime and corruption substantially reduce the economic prospects of firms. Several mechanisms can be mentioned in this respect. First, crime and corruption raise operational costs, lowering competitiveness and ultimately lowering sales. Second, crime and corruption prevent companies from entering profitable business, limiting the opportunities for growth and hence lowering sales. And finally, crime and corruption cause valuable human and financial resources to leave the companies, also limiting growth. Distinguishing between these mechanisms is admittedly very difficult, if only because they are likely to operate simultaneously.

Table 9 shows the effects of crime and corruption on investment growth. Unlike the previous results, there are no noticeable differences in investment growth between firms that report that corruption is either common in their line of business or an obstacle to doing business and firms that report the opposite. Investment growth is two percentage points (or 16 percent) lower in firms that report that crime is an obstacle to doing business than in firms that report the opposite, but this difference is not statistically significant. Table 10 repeats the exercise for employment growth. The results show that perceptions of corruption are not linked to employment growth at the firm level. Employment growth is
1.5 percentage points (or 47 percent) lower in firms that report that crime is an obstacle than in firms that do not, but this difference is not statistically significant.

Two main conclusions can be drawn from the previous analysis. First, the effects of crime and corruption upon the economic prospects of firms appear to be circumscribed to the growth sales. And second, crime appears to have a more noticeable effect on economic outcomes than corruption does. These conclusions hold up after splitting the sample into developed and developing countries and after changing the sets of controls used in the analysis. Interestingly, the relationship between economic performance and corruption is the same irrespective of the level of development of the countries under study.

The previous results suggest that the effects of crime and corruption upon economic activity are noticeable within countries. Because corruption and crime usually affect all firms in the economy (e.g., crime depresses the overall climate of business and corruption increases the cost of capital), our results are likely to underestimate the effects under
consideration. Accordingly, our results shouldn’t be interpreted as indicating that crime and corruption don’t affect investment and employment growth. Rather, what our results suggest is that if crime and corruption do affect investment and employment growth, they do it upon all firms in the economy regardless of whether or not they complain about corruption.

In sum, we can say that corruption and crime are likely to affect competitiveness, at least in term of sales growth.

V. Corruption and Bureaucratic Interference in the Private Sector Survey

Figure 5 shows that there is a high correlation between indicators of corruption, on the one hand, and regulatory burden, on the other. Both indicators were taken from Kaufmann et al. (1999). The corruption indicator was already introduced and has a straightforward interpretation. The indicator of regulatory burden includes measures of market unfriendly policies as well as perceptions of the burdens imposed by excessive regulation in areas such as foreign trade and business development.

While one can spin many different stories to account for this correlation, all of them will tend to fall into two main categories. In the first, which goes back at least to Krueger (1974), excessive government restrictions on economic activity give rise to illegal attempts by private parts to circumvent them. In the second, which has been eloquently expounded by Shleifer and Vishny (1998), restrictions on economic activity and bureaucratic procedures in general are seen as the consequence, not simply as the initiators, of rent-seeking activities. In this story, bureaucrats usually adjust government restrictions so as to maximize bribe collection and not simply take them as given.

In the first story, bureaucrats don’t have enough leeway to change government regulations (which may be the result of well-intended efforts to prevent market failures and increase

---

10 In the same vein, Djankov, La Porta, Lopez-de-Silanes and Shleifer (2000) find that countries that have stricter entry regulation also exhibits higher levels of corruption.
productivity) but can usually decide whether or not to enforce them. Bureaucrats use all the power at their discretion for personal gain; that is, they charge interested private parts for the privilege of skipping bureaucratic procedures. Examples abound. A business license authority is bribed by an entrepreneur to spare him of a lengthy registration process. A custom official is bribed by a businessman to exempt him from shipment inspections. And so on.

![Graph: Kaufmann Indicators of Corruption and Regulatory Burden](image)

An important corollary of this story is that corruption may allow private agents to buy lower effective red tape, hence reducing the detrimental effects of exaggerated government regulation. In short, corruption can be efficiency-enhancing. Lui (1985) has formalized this idea by means of a queuing model in which the presence of corruption not only allows more willing private agents to move ahead in the queue, but it also induces bureaucrats to increase the speed with which they process the queue.

In the second story, red tape and corruption are the two sides of the same coin and the efficiency-enhancing role of corruption no longer applies. The point is that government regulations are no longer an exogenous hurdle that can be partially mitigated through illegal payments, but an instrument used by bureaucrats to enlarge their bounty. In this story, unmitigated corruption not only will be harmful in terms of economic efficiency, but will
also cause obtrusive regulation to increase. While in the first model regulation begets corruption, in the second the causality reverses; it is corruption now that begets regulation.

Distinguishing between these two models is important because they imply a fundamental difference of emphasis when it comes to design anti-corruption policy interventions. According to the first model, a policy aimed at lowering corruption should focus on curtailing unnecessary government regulation. According to second story, a similarly motivated policy should focus directly on curtailing corruption, perhaps though increasing expected punishment to corrupt officials and increasing transparency in public matters. If successful, such policy should lower government regulation as well.

Unfortunately, the available cross-country evidence offers few clues as to which of these alternatives models bear closer resemblance to reality. As argued earlier, both models predict a positive connection between the extent of corruption, on the one hand, and the extent of nominal bureaucratic red tape, on the other. Empirical evidence showing that corruption is bad for growth could be interpreted as indirect evidence in favor of the second model. But this evidence is hardly enough to offer up a definitive verdict. Below, we follow Kaufmann and Wei (1999) and present firm-level evidence that can be used to distinguish between the two competing models under consideration.

Our empirical analysis focuses on the relationship between bribe payments and the amount of time wasted by senior managers dealing with bureaucrats. If the first model above applies, firm managers will be able to reduce the nominal levels of red tape by means of illegal payments. This implies that, all else equal, firms that do pay bribes will be less affected by bureaucratic interference and that hence their senior management will waste less time dealing with bureaucrats. From this, we can derive a simple hypothesis.

H1: All else equal, time wasted in bureaucratic red tape will be lower in firms that pay bribes.
However, if bureaucrats are able to modify government regulations on a firm-by-firm basis, they will impose more stringent regulations on the firms more willing to tolerate red tape and bureaucratic delay. Kaufmann and Wei (1999) use a version of the second model sketched above to show that if bureaucrats can vary nominal regulations from one firm to another, effective bureaucratic interference will be higher in firms that do pay bribes. In this model, bureaucrats customize nominal regulation, imposing the most intricate and complex restrictions on the most tolerant firms. These firms will pay higher bribes, seeking to reduce the suffocating levels of red tape forced upon them, but despite the higher bribes, they will still bear a higher effective level of red tape. From this, we can derive an alternative hypothesis.

H2: All else equal, time wasted in bureaucratic red tape will be higher in firms that pay higher bribes.

We test the previous hypotheses using data from the private sector survey. Managers in this survey were queried about what fraction of their time was spent dealing with bureaucrats. The specific question was: “what percentage of senior management’s time per year is spent in dealing with government officials about the application and interpretation of laws and regulations?” We interpret this percentage as the extent of effective bureaucratic red tape borne by each firm. Our test hinges on whether or not this percentage is higher in firms in which managers report that corruption is either an obstacle to doing business or a common practice in their line of business.

28
Table 11 shows the distribution across firms of the percentage of management’s time spent dealing with bureaucrats. Most managers (64%) report no time at all spent in these matters. The mean value of this variable is 4.6%. Surprisingly, the mean for developed countries is higher than the mean for Latin American countries (5.8% and 4.1%, respectively). Insofar as mean values are a good proxy for the extent of effective regulatory burden in a country or region, the data at hand suggests that, unlike the case of corruption, the burden of red tape is not much higher in developing countries than in developed ones.\footnote{The correlation coefficient between the country means of this variable and the Kaufmann index of regulatory burden is almost zero, suggesting that the effective and nominal levels of bureaucratic interference can be quite at odds.}

We use the following empirical model to study the interplay between effective bureaucratic red tape and corruption at the firm level:

\[ B_{ij} = c + \alpha \text{Corrup} + X_{ij} \beta + \lambda_j + \varepsilon_{ij}, \]  \hspace{1cm} (3)

where \( B_{ij} \) is the percentage of time spent dealing with bureaucrats by the senior management of firm \( i \) in country \( j \), \text{Corrup} is an indicator of corruption, \( X_{ij} \) is a vector of firm characteristics (including sector, size, tenure, location, whether the firm has foreign or state ownership, and whether the firm sell goods or services to the government), \( \lambda_j \) is a country effect and \( \varepsilon_{ij} \) is an error term. A negative value of \( \alpha \) would indicate that corruption reduces the extent of effective bureaucratic red tape (i.e., H1 is true). A positive value would indicate that corruption and bureaucratic red tape go hand in hand (i.e., H2 is true).

We control for all firm characteristics listed in Table 6, for the propensity of the respondents to complain indistinctively, and for country fixed effects. We use the same corruption and crime indicators used in the previous section. That is, corr1 (corruption is an obstacle to doing business), corr2 (corruption is common in one’s line of business), corr6 (public officials requested bribes during 1999), and crime (crime is a obstacle to doing business).\footnote{We also study the relationship between economic outcomes and the other corruption indicators defined in Section III. Neither of these indicators have a consistent relationship with economic outcomes (unreported results).} We assume that firms that answer affirmatively to these questions are more likely to pay bribes.
We estimate Equation (3) using a Tobit model. This type of empirical model is appropriate in this case because of the peculiar distribution of the dependent variable, which includes a big mass of observations at the value of zero. One can argue that respondents only reported that they did spend some time dealing with bureaucrats if such time exceeds some unknown positive value. If this assumption is true, the dependent variable will be censored and the Tobit model will have ample justification.\footnote{See, for example, Kennedy (1998).}

Table 12 presents our main results. The fraction of time wasted by senior managers dealing with red tape is larger in firms in which managers state that corruption is a significant obstacle to doing business than in firms in which managers state otherwise. On average, this fraction is more than two percentage points higher in the former than in the latter. Similarly, this fraction of time is larger in firms whose managers say that public officials requested bribes during 1999 than in firms whose managers report no bribe requests. The difference in this case is almost four percentage points; or 90% of the sample mean. By contrast, no differences are apparent between firms that report that corruption is common in their line of business and firms that report the opposite and between firms that report that crime is an obstacle and firms that report otherwise.

The previous results do not change much if other estimation methods and other sets of controls are used. The results are also very similar if the sample is restricted to either Latin America or O.E.C.D countries, which suggests that the relationship in question is not mediated by the level of development: it has the same size and sign in both developed and developing countries.

The results provide compelling evidence in favor of the second hypothesis presented above. There appears to be a positive connection between bribe payments and effective bureaucratic delay at the firm level. The same result was obtained by Kaufmann and Wei (1999) using a similar empirical strategy and data from three distinct private surveys: the 1996 and 1997 surveys for the Global Competitiveness Report and the 1997 survey for the World Development Report. Taken together, these results suggest that public officials are able to manipulate nominal bureaucratic restrictions so as to increase bribe collection. Thus, nominal regulations should not be considered exogenously given but endogenously determined by corrupt officials seeking to extract higher bribes from private business.

Our empirical results are broadly consistent with the idea that regulation is mainly a mechanism to create rents for bureaucrats. Economic regulations shouldn’t then be perceived simply as well-intended attempts to prevent market failures and increase productivity that can inadvertently create corruption. Rather, they should be perceived as devises to transfer rents from firms and individuals to bureaucrats.¹⁴

VI. Conclusions

This paper examines both the effects of corruption and crime on the economic outcomes of firms and the link between corruption and effective bureaucratic interference at the firm level.
The results show that corruption has a noticeable effect on the economic outcomes of firms in the sense that these outcomes tend to be lower in firms where managers report that corruption is an obstacle to doing business than in firms where managers report otherwise. In the same vein, the results show that crime has a similar (if not higher) effect on the economic outcomes of firms. Both effects are noticeable even after taking into account firm and country characteristics. On the whole, the evidence indicates that corruption and crime substantially reduce competitiveness.

The results also indicate that corruption and effective bureaucratic interference (measured as the fraction of senior management's time spent dealing with bureaucrats) go hand in hand. That is, bureaucratic interference is higher in firms that are more likely to pay bribes. This result flies in the face of several theories that predict that bribes can increase efficiency by allowing firms to avoid exaggerated government regulations. The results suggest, in contrast, that government regulations are strategically used by bureaucrats to maximize bribe collection.

Finally, the results show that that corruption and crime differ substantially from one country to the next, and that they are tightly associated. Government arbitrariness in the form of corruption and inability to enforce contracts and protect property rights are the flip sides of the same problem—a problem that affects all types of firms, irrespective of their area of business, location and type of ownership, and that constitutes, without a doubt, one of the most serious hurdles to private entrepreneurship in developing countries.

14 See Shleifer and Vishny (1998) for an eloquent and powerful exposition of this view, referred to them as the Grabbing Hand hypothesis.
